The metacentric height (GM) is a measurement of the initial static stability of a floating body.It is calculated as the distance between the centre of gravity of a ship and its metacentre.A larger metacentric height implies greater initial stability against overturning. The metacentric height also influences the natural period of rolling of a hull, with very large metacentric heights being ...

The GM value is a measure of the vessel's stability under small heeling, also called initial stability. The higher the GM value, the better the vessel's initial stability and the harder it is to get the vessel to heel. A vessel with a large GM value can be described as a rigid vessel that rolls fast on sea.
